Application No.: 10/645,354 Docket No.: 87319.4561

Customer No.: 30734

LISTING OF THE CLAIMS:

A complete listing of the claims is provided below. This listing of claims will replace all

prior versions, and listings, of claims in the application.

1. (Original) A rapidly responding, false detection immune smoke detector of a

light obscuration type, comprising:

a light source from which a light beam propagates;

a light detector having a light receiving surface with a light detecting area and

producing a signal in response to light incident on the light receiving surface; and

a light reflective imaging assembly in optical association with the light source and the

light detector, the imaging assembly including first and second spaced-apart optical components

having respective first and second opposed light reflecting surfaces forming between them a

spatial region that smoke particles can occupy, the first and second optical components having

light directing properties that cooperate to reflect the light beam between the first and second

light reflecting surfaces and to direct the light beam toward the light detector for incidence on its

light receiving surface, and the first and second optical components controlling the light beam by

providing it with a beam width that is sufficiently wide to render insignificant contributions of

anomalous light reflections but that converges to illuminate the light receiving surface within the

confines of the light detecting area and thereby cause the light detector to produce a signal

corresponding to a concentration of the smoke particles occupying the spatial region.

2. (Original) The smoke detector of claim 1, further comprising a rate of change

measurement detector operatively associated with the light detector to measure a rate of change

Application No.: 10/645,354

Docket No.: 87319.4561

Customer No.: 30734

of the concentration of smoke particles occupying the spatial region, the rate of change

measurement detector responding to the signal produced by the light detector to determine an

elapsed time between changes in concentrations of smoke particles between first and second

smoke concentration threshold levels.

3. (Original) The smoke detector of claim 2, in which the first smoke concentration

threshold level is less than the second smoke concentration threshold level and the rate of

change measurement detector produces a signal indicating that a rate of rise of the concentration

of smoke particles from the first smoke concentration threshold level to the second smoke

concentration threshold level has exceeded a first predetermined threshold rate and the

concentration of smoke particles persists above the second smoke concentration threshold level

for a predetermined time.

4. (Currently Amended) A rapidly responding, false detection immune smoke

detector of a light obscuration type, comprising:

a light source from which a light beam propagates;

a light detector having a light receiving surface with a light detecting area and

producing a signal in response to light incident on the light receiving surface;

a light reflective imaging assembly in optical association with the light source and

the light detector, the imaging assembly including first and second spaced-apart optical

components having respective first and second opposed light reflecting surfaces forming

between them a spatial region that smoke particles can occupy, the first and second optical

components having light directing properties that cooperate to reflect the light beam between

the first and second light reflecting surfaces and to direct the light beam toward the light

Application No.: 10/645,354

Docket No.: 87319.4561

Customer No.: 30734

detector for incidence on its light receiving surface, and the first and second optical

components controlling the light beam by providing it with a beam width that is sufficiently

wide to render insignificant contributions of anomalous light reflections but that converges to

illuminate the light receiving surface within the confines of the light detecting area and thereby

cause the light detector to produce a signal corresponding to a concentration of the smoke

particles occupying the spatial region;

a rate of change measurement detector operatively associated with the light detector

to measure a rate of change of the concentration of smoke particles occupying the spatial region,

the rate of change measurement detector responding to the signal produced by the light detector

to determine an elapsed time between changes in concentrations of smoke particles between

first and second smoke concentration threshold levels, wherein the first smoke concentration

threshold level is less than the second smoke concentration threshold level and the rate of

change measurement detector produces a signal indicating that a rate of rise of the concentration

of smoke particles from the first smoke concentration threshold level to the second smoke

concentration threshold level has exceeded a first predetermined threshold rate and the

concentration of smoke particles persists above the second smoke concentration threshold level

for a predetermined time; and The smoke detector of claim 3, further comprising

an alarm threshold circuit to which an alarm smoke concentration threshold level is

set, and in which the first smoke concentration threshold level is less than the alarm smoke

concentration threshold level.

5. (Currently Amended) A rapidly responding, false detection immune smoke

detector of a light obscuration type, comprising:

a light source from which a light beam propagates;

Customer No.: 30734

a light detector having a light receiving surface with a light detecting area and

producing a signal in response to light incident on the light receiving surface;

a light reflective imaging assembly in optical association with the light source and

the light detector, the imaging assembly including first and second spaced-apart optical

components having respective first and second opposed light reflecting surfaces forming

between them a spatial region that smoke particles can occupy, the first and second optical

components having light directing properties that cooperate to reflect the light beam between the

first and second light reflecting surfaces and to direct the light beam toward the light detector

for incidence on its light receiving surface, and the first and second optical components

controlling the light beam by providing it with a beam width that is sufficiently wide to render

insignificant contributions of anomalous light reflections but that converges to illuminate the

light receiving surface within the confines of the light detecting area and thereby cause the light

detector to produce a signal corresponding to a concentration of the smoke particles occupying

the spatial region; and

a rate of change measurement detector operatively associated with the light detector

to measure a rate of change of the concentration of smoke particles occupying the spatial region,

the rate of change measurement detector responding to the signal produced by the light detector

to determine an elapsed time between changes in concentrations of smoke particles between first

and second smoke concentration threshold levels, The smoke detector of claim 2, in which

wherein the first smoke concentration threshold level is less than the second smoke

concentration threshold level and the rate of change measurement detector produces a signal

indicating that a rate of rise of the concentration of smoke particles from the first smoke

concentration threshold level to the second smoke concentration threshold level is less than a

Application No.: 10/645,354

Docket No.: 87319.4561

Customer No.: 30734

second predetermined threshold rate to indicate a long-term degradation of intensity of light

incident on the light receiving surface of the light detector.

6. (Currently Amended) A rapidly responding, false detection immune smoke

detector of a light obscuration type, comprising:

a light source from which a light beam propagates;

a light detector having a light receiving surface with a light detecting area and

producing a signal in response to light incident on the light receiving surface; and

a light reflective imaging assembly in optical association with the light source and

the light detector, the imaging assembly including first and second spaced-apart optical

components having respective first and second opposed light reflecting surfaces forming

between them a spatial region that smoke particles can occupy, the first and second optical

components having light directing properties that cooperate to reflect the light beam between the

first and second light reflecting surfaces and to direct the light beam toward the light detector

for incidence on its light receiving surface, and the first and second optical components

controlling the light beam by providing it with a beam width that is sufficiently wide to render

insignificant contributions of anomalous light_reflections but that converges to illuminate the

light receiving surface within the confines of the light detecting area and thereby cause the light

detector to produce a signal corresponding to a concentration of the smoke particles occupying

the spatial region, wherein The smoke detector of claim 1, in which the light directing properties

of the first and second optical components cooperate to reflect the light beam multiple times

between the first and second light reflecting surfaces to establish a smoke detection sensitivity

for the smoke detector.

Application No.: 10/645,354

Docket No.: 87319.4561

Customer No.: 30734

7. (Original) The smoke detector of claim 1, in which one of the first and second light

reflecting surfaces includes a pair of openings, the light beam emitted by the light source

propagating through one of the pair of openings and the light beam received by the light detector

after incidence on the first and second light reflecting surfaces propagating through the other

one of the pair of openings.

8. (Currently Amended) A rapidly responding, false detection immune smoke

detector of a light obscuration type, comprising:

a light source from which a light beam propagates;

a light detector having a light receiving surface with a light detecting area and

producing a signal in response to light incident on the light receiving surface; and

a light reflective imaging assembly in optical association with the light source and the light

detector, the imaging assembly including first and second spaced-apart optical components

having respective first and second opposed light reflecting surfaces forming between them a

spatial region that smoke particles can occupy, the first and second optical components having

light directing properties that cooperate to reflect the light beam between the first and second

light reflecting surfaces and to direct the light beam toward the light detector for incidence on

its light receiving surface, and the first and second optical components controlling the light

beam by providing it with a beam width that is sufficiently wide to render insignificant

contributions of anomalous light reflections but that converges to illuminate the light

receiving surface within the confines of the light detecting area and thereby cause the light

detector to produce a signal corresponding to a concentration of the smoke particles

occupying the spatial region, wherein one of the first and second light reflecting surfaces

includes a pair of openings, the light beam emitted by the light source propagating through one

PATENT Application No.: 10/645,354

Docket No.: 87319.4561

Customer No.: 30734

of the pair of openings and the light beam received by the light detector after incidence on the

first and second light reflecting surfaces propagating through the other one of the pair of

openings and wherein The smoke detector of claim 7, in which an optical axis extends

between the first and second light reflecting surfaces and in which the openings included in the

pair are positioned on opposite sides of the optical axis.

9. (Original) The smoke detector of claim 1, in which the opposed first and second

light reflecting surfaces have surface normals and in which the first and second light reflecting

surfaces are positioned so that their surface normals are parallel to each other.

10. (Original) The smoke detector of claim 1, in which the first light reflecting surface

is curved, the first optical component has an opposite surface, and the light source and

the

light detector are positioned in proximity to the opposite surface of the first optical component.

11. (Original) The smoke detector of claim 1, in which the first and second

light reflecting surfaces are curved.

12. (Original) The smoke detector of claim 11, in which each of the first and

second optical components has an opposite surface, and one of the opposite surfaces is

positioned in proximity to the light source and the light detector.

13. (Original) The smoke detector of claim 1, in which one of the first and second

light reflecting surfaces is in the form of a concave optical surface and the other of the first

and second light reflecting surfaces is in the form of a piano optical surface.

Application No.: 10/645,354 Docket No.: 87319.4561

Customer No.: 30734

14. (Original) The smoke detector of claim 13, in which the concave optical surface is of spherical shape with a surface normal at an apex, the spherical optical surface being positioned so that its surface normal is normal to the piano optical surface.

15. (Currently Amended) A rapidly responding, false detection immune smoke detector of a light obscuration type, comprising:

a light source from which a light beam propagates;

a light detector having a light receiving surface with a light detecting area and producing a signal in response to light incident on the light receiving surface; and

a light reflective imaging assembly in optical association with the light source and the light detector, the imaging assembly including first and second spaced-apart optical components having respective first and second opposed light reflecting surfaces forming between them a spatial region that smoke particles can occupy, the first and second optical components having light directing properties that cooperate to reflect the light beam between the first and second light reflecting surfaces and to direct the light beam toward the light detector for incidence on its light receiving surface, and the first and second optical components controlling the light beam by providing it with a beam width that is sufficiently wide to render insignificant contributions of anomalous light reflections but that converges to illuminate the light receiving surface within the confines of the light detecting area and thereby cause the light detector to produce a signal corresponding to a concentration of the smoke particles occupying the spatial region, wherein one of the first and second light reflecting surfaces is in the form of a concave optical surface and the other of the first and second light reflecting surfaces is in the form of a piano optical surface and wherein The

Application No.: 10/645,354 PATENT

Docket No.: 87319.4561 Customer No.: 30734

smoke-detector of claim 13, in-which the first and second light reflecting surfaces are

spaced apart by a distance to define a path length, and in which the concave optical surface

has a focal length that is about twice the path length and an effective beam length that is

about six times the path length.

16. (Original) The smoke detector of claim 1, in which an optical axis extends

between the first and second light reflecting surfaces and in which, for at least one of the first

and second light reflecting surfaces, the multiple reflections undergone by the light beam take

place on both sides of the optical axis.

17. (Original) The smoke detector of claim 1, in which the light beam reflects off at

least one of the first and second reflecting surfaces multiple times before the light beam is

incident on the light detector.

18. (Original) The smoke detector of claim 1, in which the light source includes a

light-emitting diode.

19. (Original) The smoke detector of claim 18, in which the light-emitting diode

emits light having a wavelength of less than about 800 nm.

20. (Original) The smoke detector of claim 1, in which the light beam is

within a wavelength range of between about 350 nm and about 470 nm.

21. (Original) The smoke detector of claim 1, in which the light reflective

imaging assembly is in the form of an integral unit.

Customer No.: 30734

22. (Original) A rapidly responding, false detection immune smoke detector of a

light obscuration type, comprising:

a light reflective imaging assembly including a pair of spaced-apart, opposed light

reflecting surfaces between which a concentration of smoke particles can enter;

a light source from which a light beam propagates in a direction for reflection by

the light reflecting surfaces, the light beam reflecting off each one of the pair of light

reflecting surfaces as it propagates through the light reflective imaging assembly, the light

beam exiting the light reflective imaging assembly having an intensity corresponding to the

concentration of smoke particles present between the light reflecting surfaces; and

a light detector positioned to receive a light beam representing the

concentration of smoke particles in the light reflective imaging assembly.

23. (**Original**) The smoke detector of claim 22, further comprising:

a light source modulator providing to the light source a sampling sequence of pulses

that cause intermittent propagation of the light beam, the sampling sequence including an ON

interval during which a first group of pulses causes the light beam to propagate and an OFF

interval during which the light beam does not propagate;

the detector receiving the light beam representing the concentration of smoke

particles and producing an ON state output signal during the ON interval and an OFF state

output signal during the OFF interval, the ON state and OFF state output signals having a

common background noise signal component; and

a signal conditioner receiving the ON state and OFF state output signals and

removing the common background noise signal component to produce a noise-corrected

Application No.: 10/645,354 **PATENT**

Docket No.: 87319.4561

Customer No.: 30734

signal value representing the concentration of smoke particles present between the light

reflecting surfaces during the sampling sequence.

24. (Original) The smoke detector of claim 23, in which the signal conditioner

removes the common background noise signal component by computing average ON state

output signal values and average OFF state output signal values and subtracting them to

produce the noise-corrected signal value.

25. (Original) A false detection immune, light obscuration type smoke detector

that is capable of detecting particles of different sizes, comprising:

a light reflective imaging assembly including a pair of spaced-apart, opposed

light reflecting surfaces between which gas-borne particles can enter;

first and second light sources from which, respective first and second light beams

of different wavelengths propagate in directions for reflection by the light reflecting surfaces,

the first and second light beams reflecting off each one of the pair of light reflecting surfaces as

the first and second light beams propagate through the light reflective imaging assembly, the

first and second light beams exiting the light reflective imaging assembly having intensities

corresponding to concentrations of gas-borne particles of different ranges of sizes present between

the light reflecting surfaces, the first and second ranges of sizes being determined by the

wavelengths of, respectively, the first and second light beams; and

a light detector positioned to receive a light beam representing at least one of the

first and second ranges of sizes of the gas-borne particles in the light reflective imaging assembly.

26. (Original) The smoke detector of claim 25, further comprising pulse circuitry

operatively associated with the first and second light sources to produce for reception by the

Application No.: 10/645,354

Docket No.: 87319.4561

Customer No.: 30734

light detector the light beam carrying noncoincident representations of the first and second ranges

of sizes of the gas-borne particles.

27. (Original) The smoke detector of claim 25, in which the wavelength of the first

light beam is less than about 500 nm.

28. (Original) The smoke detector of claim 27, in which the wavelength of the

second light beam is greater than about 800 nm.

29. (Original) The smoke detector of claim 25, in which the first and second

wavelengths are, respectively, less than about 500 nm and greater than about 800 nm, in which

the light detector constitutes a first light detector, and in which the light beam constitutes a first

measurement light beam representing the first range of sizes of gas-borne particles, so that the

first light detector receives the first measurement light beam, and further comprising:

a second light detector that receives a second measurement light beam

representing the second range of sizes of gas-borne particles; and

a discriminator that receives signals produced by the first and second light

detectors and corresponding to the respective first and second measurement light beams, the

discriminator determining average sizes of the gas-borne particles present between the light

reflecting surfaces and thereby distinguishing the gas-borne particles from one another by

their origins as indicated by their sizes.

30. (Original) A smoke detector of an obscuration type configured for placement of its

optical components within the interior of an air duct having a duct side wall with an exterior

surface, the smoke detector monitoring the quality of air flowing in an air flow direction through

Application No.: 10/645,354 PATENT

Docket No.: 87319.4561

Customer No.: 30734

the interior of the air duct, comprising:

a light reflective imaging assembly including a pair of spaced-apart, opposed light

reflecting surfaces between which a concentration of smoke particles can enter and an optical

axis extends;

a support configured to extend through an opening in the duct side wall and having

first and second ends, the first end holding the light reflective assembly within the interior of the

air duct in a desired orientation that positions the optical axis transversely of the direction of air

flow within the air duct, and the second end being mechanically coupled to the side wall to

secure the support and thereby set the light reflective assembly in the desired orientation;

a light source from which a light beam propagates in a direction for reflection by

the light reflecting surfaces, the light beam reflecting off each one of the pair of light

reflecting surfaces as it propagates through the light reflective imaging assembly, the light

beam exiting the light reflective imaging assembly having an intensity corresponding to the

concentration of smoke particles present between the light reflecting surfaces; and

a light detector positioned to receive a light beam representing the

concentration of smoke particles in the light reflective imaging assembly.

31. (Original) The smoke detector of claim 30, in which the light source and the

light detector are mounted within the interior of the air duct and adjacent the light reflective

imaging assembly.

32. (Original) The smoke detector of claim 30, further comprising an alarm control

circuit contained in a temperature resistant housing that is coupled to the second end

of the support and mounted with a temperature resistant seal on the exterior surface of the duct

Docket No.: 87319.4561 Customer No.: 30734

Application No.: 10/645,354

side wall.

33. (Original) The smoke detector of claim 30, in which the support includes a

tubular arm that extends through the opening in the duct side wall and into the interior of the air

duct.

34. (Original) The smoke detector of claim 33, further comprising an alarm control

circuit that is coupled to the second end of the support, in which the light detector is held in

position by the support and within the interior of the air duct, and in which the tubular arm

provides a conduit for a communication link between the light detector and the alarm control

circuit.

35. (Original) A rapidly responding, false detection immune smoke detector of a

light obscuration type, comprising:

a light source from which a light beam propagates;

a light detector having a light receiving surface with a light detecting area and

producing a signal in response to light incident on the light receiving surface;

a light reflective imaging assembly in optical association with the light source and

the light detector, the imaging assembly including first and second spaced-apart optical

components having respective first and second opposed light reflecting surfaces forming

between them a spatial region that smoke particles can occupy, the first and second optical

components having light directing properties that cooperate to reflect the light beam between

the first and second light reflecting surfaces and to direct the light beam toward the light

detector for incidence on its light receiving surface and thereby cause the light detector to

Application No.: 10/645,354 **PATENT**

Docket No.: 87319.4561

Customer No.: 30734

produce a signal corresponding to a concentration of the smoke particles occupying the spatial

region; and

circuitry operatively associated with the light detector to acquire during a data

gathering time interval data from the signal corresponding to the concentration of the smoke

particles occupying the spatial region, the data gathering time interval being long as compared

to the time of a slow fire, and the circuit determining an adjustment value for application to the

signal produced by the light detector in response to a change in the acquired data that, in the

absence of smoke, is greater than a preassigned operational tolerance after the data gathering

time interval.
